Collaboration: Jacob Reed, Jamie Foster, Varun Narayanswamy, Simon Koeten
CSCI 3104, Algorithms **Profs. Hoenigman & Agrawal**
Problem Set 9b (51 points) **Fall 2019, CU-Boulder**

Advice 1: For every problem in this class, you must justify your answer: show how you arrived at it and why it is correct. If there are assumptions you need to make along the way, state those clearly.

Advice 2: Verbal reasoning is typically insufficient for full credit. Instead, write a logical argument, in the style of a mathematical proof.

Instructions for submitting your solution:

- The solutions **should be typed** and we cannot accept hand-written solutions. Here's a short intro to Latex.
- You should submit your work through **Gradescope** only.
- If you don't have an account on it, sign up for one using your CU email. You should have gotten an email to sign up. If your name based CU email doesn't work, try the identikey@colorado.edu version.
- Gradescope will only accept **.pdf** files (except for code files that should be submitted separately on Gradescope if a problem set has them) and **try to fit your work in the box provided**.
- You cannot submit a pdf which has less pages than what we provided you as Gradescope won't allow it.

Name: Alex Book

Collaboration: Jacob Reed, Jamie Foster, Varun Narayanswamy, Simon Koeten
CSCI 3104, Algorithms **Profs. Hoenigman & Agrawal**
Problem Set 9b (51 points) **Fall 2019, CU-Boulder**

Important: This assignment has 1 (Q2) coding question.

- You need to submit 1 python file.
- The .py file should run for you to get points and name the file as following -
If Q2 asks for a python code, please submit it with the following naming convention -
Lastname-Firstname-PS9b-Q2.py.
- You need to submit the code via Canvas but the table/plot/result should be on the main .pdf.

Problem Set 9b (51 points) **Fall 2019, CU-Boulder**

1. (21 pts) The sequence P_n of Pell numbers is defined by the recurrence relation

$$P_n = 2P_{n-1} + P_{n-2} \quad (1)$$

with seed values $P_0 = 1$ and $P_1 = 1$.

- (a) (5 pts) Consider the recursive top-down implementation of the recurrence (1) for calculating the n -th Pell number P_n .

- i. Write down an algorithm for the recursive top-down implementation in pseudocode.

Solution.

```
def PellNum(n):
    if n==0 or n==1:
        return 1
    else:
        return 2*PellNum(n-1)+PellNum(n-2)
```

- ii. Draw the tree of function calls to calculate P_5 . You can call your function f in this diagram.

Solution.

- iii. Write down the recurrence for the running time $T(n)$ of the algorithm.

Solution.

$$T(n) = T(n-1) + T(n-2) + \Theta(1)$$

Problem Set 9b (51 points) Fall 2019, CU-Boulder

- (b) (6 pts) Consider the dynamic programming approach “top-down implementation with memoization” that memoizes the intermediate Pell numbers by storing them in an array $P[n]$.

- i. Write down an algorithm for the top-down implementation with memoization in pseudocode.

Solution.

```
PellArray=[1,1]
def PellNum(n):
    if len(PellArray)-1 >= n:
        return PellArray[n]
    a=2*PellNum(n-1)+PellNum(n-2)
    PellArray.append(a)
    return a
```

- ii. Draw the tree of function calls to calculate P_5 . You can call your function f in this diagram.

Solution.

- iii. In order to find the value of P_5 , you would fill the array P in a certain order. Provide the order in which you will fill P showing the values.

Solution.

$P[1]=1, P[0]=1, P[2]=3, P[3]=7, P[4]=17, P[5]=41$

- iv. Determine and justify briefly the asymptotic running time $T(n)$ of the algorithm.

Solution.

The asymptotic running time is $O(n)$ because each necessary Pell value is only calculated one time and stored. Every reference after that, it is simply accessed from the storage array, which happens in constant time.

CSCI 3104, Algorithms

Profs. Hoenigman & Agrawal

Fall 2019, CU-Boulder

- i. Write down an algorithm for the iterative bottom-up implementation in pseudocode.

```
def PellNum(n):
    PellArray=[]
    for i in range(n+1):
        if i==0 or i==1:
            PellArray.append(1)
        else:
            PellArray.append(2*PellArray[i-1]+PellArray[i-2])
    return PellArray[-1]
```

- Solution.*

$$P[0]=1, P[1]=1, P[2]=3, P[3]=7, P[4]=17, P[5]=41$$

- Solution.*

CSCI 3104, Algorithms

Profs. Hoenigman & Agrawal

Problem Set 9b (51 points)

Fall 2019, CU-Boulder

- (d) (3 pts) If you only want to calculate P_n , you can have an iterative bottom-up implementation with $\Theta(1)$ space usage. Write down an iterative algorithm with $\Theta(1)$ space usage in pseudocode for calculating P_n . There is no requirement for the runtime complexity of your algorithm. Justify your algorithm does have $\Theta(1)$ space usage.

Solution.

```
def PellNum(n):
    minus2=0
    minus1=0
    current=0
    for i in range(n+1):
        if i==0 or i==1:
            minus2=1
            minus1=1
            current=1
        else:
            current=2*minus1+minus2
            minus2=minus1
            minus1=current
    return current
```

This algorithm has a space complexity of $\Theta(1)$ because only three variables are written to and read from in order to find the Pell number for n , regardless of the value of n .

CSCI 3104, Algorithms **Profs. Hoenigman & Agrawal**

Problem Set 9b (51 points) **Fall 2019, CU-Boulder**

- (e) (2 pts) In a table, list each of the four algorithms as rows and in separate columns, provide each algorithm's asymptotic time and space requirements. Briefly discuss how these different approaches compare, and where the improvements come from.

	Algorithm	Time complexity	Space complexity
<i>Solution.</i>	1a	$O(2^n)$	$O(1)$
	1b	$O(n)$	$O(n)$
	1c	$O(n)$	$O(n)$
	1d	$O(n)$	$O(1)$

As evidenced by the table, the algorithm from part d is the optimal solution among those produced. One main difference is that it doesn't need to store every Pell value previous to the target, but only the two values previous to the current value being considered, as well as the current value itself, which allows a space complexity of $O(1)$. Another differentiating factor lies in the algorithm's lack of repeated references to various Pell values due to its use of dynamic programming, allowing a running time of $O(n)$.

All other solutions (from parts a, b, and c) either store all Pell values or repeatedly reference values. The lack of those time- and space-intensive techniques puts the algorithm from part d ahead of the rest.

2. (10 pts) Write a single python code for the following. There is a very busy student at CU who is taking CSCI 3104. They know that this course has a ton of homework and they don't want to attempt all of the homework. This student cherishes the downtime and has **decided not to do any two consecutive assignments**.

Assume that the student gets a list of assignments with the points associated at the beginning of the semester. Use dynamic programming to pick which assignments to complete to maximize the available points while not solving any two consecutive assignments.

Input: [2,7,9,3,1]

Output: 12

Explanation: Maximum points available = $2 + 9 + 1 = 12$.

- (a) (2 pts) Show an example with at least 4 assignments to show why the greedy strategy

$\max(\text{sum}(\text{even_indexed_terms}), \text{sum}(\text{odd_indexed_term}))$ does not work.

Example - For the above list, $\text{sum}(\text{even_indexed_terms}) = 2 + 9 + 1$ and

$\text{sum}(\text{odd_indexed_terms}) = 7 + 3$. But, coincidentally their \max gives out the optimal answer. You have to provide an example where this doesn't work.

Solution.

Input: [10,1,2,9]

Greedy Output: $10 + 2 = 12$

Optimal: $10 + 9 = 19$

- (b) (4 pts) Write the bottom-up DP table filling version that takes the list of assignments and outputs the maximum points that the student can attempt. (If it helps, you can code the recursive approach for practice but you don't need to submit that)

- (c) (4 pts) Write the DP version for part (b) which uses $O(1)$ space.

Note that you don't have to submit anything for part (b) and (c) on the pdf but only the commented code in the python file.

Problem Set 9b (51 points) Fall 2019, CU-Boulder

3. (10 pts) Suppose we are trying to create an optimal health shake from a number of ingredients, which we label $\mathcal{I} = \{1, \dots, n\}$. Each cup of an ingredient contributes p_i units of protein, as well as c_i calories. Our goal is to maximize the amount of protein, such that the shake uses no more than C calories. **Note that you can use more than one cup of each ingredient.**

- Design an DP based algorithm which takes the arrays p and c and calories C as input and outputs the maximum protein you can put using no more than C calories.
- In order to fill a particular table entry, you would need to access some sub-problems. Explain briefly which decisions each of those sub-problems represent.
- Also, provide the runtime and space requirement of your algorithm.

Solution.

```
def healthShake(p,c,C):
    #create empty 2D array full of zeros
    bestShakes = [[0 for i in range(C+1)] for j in range(len(p)+1)]
    #start for loops at 1 in order to skip the base case rows and columns
    for i in range(1,len(p)+1): #i is ingredient being considered
        protein=p[i-1] #keeps track of protein for ingredient being considered
        calories=c[i-1] #keeps track of calories for ingredient being considered
        for j in range(1,C+1): #j is capacity being considered
            if calories > j:
                #need to use max. protein from previous ingredient consideration
                bestShakes[i][j]=bestShakes[i-1][j]
            else:
                #need to take max. protein from either previous ingredient
                #consideration or the value that would come before the
                #current (one ingredient earlier and capacity minus current
                #ingredient's calories
                bestShakes[i][j]=max(bestShakes[i-1][j],
                    protein+bestShakes[i-1][j-calories])
    return bestShakes[len(p)][C]
```

Name: Alex Book

Collaboration: Jacob Reed, Jamie Foster, Varun Narayanswamy, Simon Koeten
CSCI 3104, Algorithms **Profs. Hoenigman & Agrawal**
Problem Set 9b (51 points) **Fall 2019, CU-Boulder**

Solution.

In order to fill any given table entry, you need to access a maximum of two different subproblems (only one if the current ingredient's calories won't be compatible with a solution). One of these subproblems is the solution cell for the same capacity and when considering one less ingredient. The other subproblem being the solution cell for the capacity minus the current ingredient's calories and when considering one less ingredient.

Consider the length of the strings p and c to be represented by the letter n . The runtime for the algorithm is $O(n * C)$ because it must fill all values of the solution array in order to get the final optimal protein shake value (which is the value at array index `bestShakes[len(p)][C]`, the last value filled). The space requirement is also $O(n * C)$ because in order to calculate the optimal protein shake value, the entire solution array must be filled, taking up $n * C$ space.

Problem Set 9b (51 points) Fall 2019, CU-Boulder

4. (10 pts) In recitation you learnt the longest common sub-sequence (LCS) problem, where you used a DP table to find the length of the LCS and to recover the LCS (there might be more than one LCS of equal length). For example - For two sequences $X = \{A, B, C, B, D, A, B\}$ and $Y = \{B, D, C, A, B, A\}$. Here's a complete solution. Grey cells represent one of the LCS (BCBA) and the red-bordered cells represent another (BCAB). Note that you have to provide only one optimal solution.

		j	0	1	2	3	4	5	6
i	x_i	y_j		B	D	C	A	B	A
0			0	0	0	0	0	0	0
1	A		0	0	0	0	1	←1	1
2	B		0	1	←1	←1	1	2	←2
3	C		0	1	1	2	←2	2	2
4	B		0	1	1	2	2	3	←3
5	D		0	1	2	2	2	3	3
6	A		0	1	2	2	3	3	4
7	B		0	1	2	2	3	4	4

- (a) (6 pts) Draw the complete table for $X = \{A, B, A, C, D\}$ and $Y = \{B, A, D, B, C, A\}$.
- Fill in all the values and parent arrows.
 - Backtrack and circle all the relevant cells to recover the actual LCS and not only the length. Do not forget to circle the appropriate characters too.
 - Report the length of the LCS and the actual LCS.

 Problem Set 9b (51 points) Fall 2019, CU-Boulder

	y	B	(A)	D	(B)	C	(A)
x	0	0	0	0	0	0	0
(A)	0	0	1	1	1	1	1
(B)	0	1	1	1	2	2	2
(A)	0	1	2	2	2	2	3
C	0	1	2	2	2	3	3
D	0	1	2	3	3	3	3

Solution.

LCS = 'ABA'

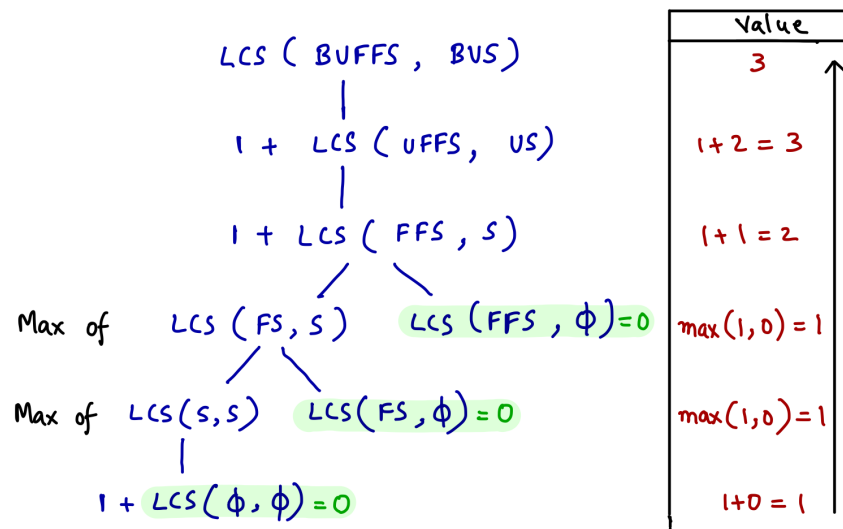

Length of LCS = 3

Name: Alex Book

ID: 108073300

Collaboration: Jacob Reed, Jamie Foster, Varun Narayanswamy, Simon Koeten
 CSCI 3104, Algorithms Profs. Hoenigman & Agrawal
 Problem Set 9b (51 points) Fall 2019, CU-Boulder

- (b) (4 pts) If you draw the recursive tree for the recursive version of LCS, you will get something like this. Here we show all the recursive calls till the base case and

annotate the children calls with a 'Max' or a '+' while indicating the base case calls. We also compute the values from bottom to top as we get them. Draw a tree like above for the LCS calls for string 'SFUB' and 'SUB' i.e. $LCS(SFUB, SUB)$.

Solution.
